QUIET OPS // LEAVE-BEHIND

Why Standard AI Is Not Safe Enough to Make Operational Decisions

Five questions to answer before you hand any job to AI

The job: _____

1 What does one wrong result cost?
Money, a customer, a deadline. If you cannot put a number or a name on it, say so.

2 Which part of the job can be written as a plain yes or no rule?
Example: hold any invoice over twice the agreed amount.

3 What is the uncertain case, and who sees it, with what in front of them?
The person needs the reason, not just the item.

4 What would a different route to the same wrong result look like?
A payment split in two to slip under a limit is the same act by another route.

5 What happens at two in the morning on a Saturday if nobody is watching?
If the answer is a guess, the job is not ready to run unattended.

HOW TO READ YOUR ANSWERS

Wrong result is cheap and the rules are clear: start here, beside the person who owns the job.

Wrong result is costly, or you cannot name the rule: write the rule first, or keep a person in the step.

Cannot answer question 5: the job is not ready to run unattended.

The work goes ahead. Only what should not is stopped.

Four levels, deterministic to subjective: fixed rules, judgment, risk rating, human in the loop. Quiet Ops: field notes from a COO. Eric Hollebone. More: github.com/e-hollebone/offers/tree/main/safe-ai-for-operational-decisions
